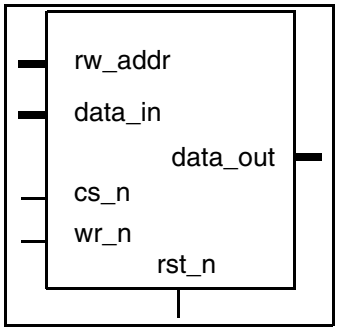
DW_ram_rw_a_lat

Asynchronous Single-Port RAM (Latch-Based)

Version, STAR and Download Information: IP Directory

Features and Benefits

- Parameterized word depth
- Parameterized data width
- Asynchronous static memory
- Parameterized reset implementation



Description

DW_ram_rw_a_lat implements a parameterized, asynchronous, single-port static RAM.

Table 1-1 Pin Description

Pin Name	Width	Direction	Function
rst_n	1 bit	Input	Reset, active low
cs_n	1 bit	Input	Chip select, active low
wr_n	1 bit	Input	Write enable, active low
rw_addr	ceil($\log_2$[*depth*]) bit(s)	Input	Address bus
data_in	*data_width* bit(s)	Input	Input data bus
data_out	*data_width* bit(s)	Output	Output data bus

Table 1-2 Parameter Description

Parameter	Values	Description
data_width	1 to 256 Default = none	Width of `data_in` and `data_out` buses
depth	2 to 256 Default = none	Number of words in the memory array (address width)
rst_mode	0 or 1 Default = 1	Determines if the `rst_n` input is used. 0 = `rst_n` initializes the RAM, 1 = `rst_n` is not connected

Table 1-3 Synthesis Implementations

Implementation Name	Function	License Feature Required
str	Synthesis model	DesignWare

Table 1-4 Simulation Models

Model	Function
DW06.DW_RAM_RW_A_LAT_CFG_SIM	VHDL simulation configuration
dw/dw06/src/DW_ram_rw_a_lat_sim.vhd	VHDL simulation model source code
dw/sim_ver/DW_ram_rw_a_lat.v	Verilog simulation model source code

The write data enters the RAM through the `data_in` input port, and is read out at the `data_out` port. The RAM is constantly reading regardless of the state of `cs_n`.

The `rw_addr` port is used to address the *depth* words in memory. For addresses beyond the maximum depth (for example, `rw_addr` = 7 hex and `depth` = 6), the `data_out` bus is driven LOW. No warnings are given during simulations when an address beyond the scope of *depth* is used.

Attention This component contains enable signals for internal latches that are derived from the wr_n port. To keep hold times to a minimum, you should consider instances of this component to be individual floorplanning elements

Chip Selection, Reading and Writing

The `cs_n` input is the chip select, active low signal that enables the RAM to always be read.

When `cs_n` and `wr_n` (write enable, active low) are both LOW, the `data_in` is transparent to the memory cell being accessed (`data_in` equals `data_out`). Data is captured into the memory cell on the LOW to HIGH transition of `wr_n`.

When `cs_n` is HIGH, the RAM is disabled, and the `data_out` bus is driven LOW.

Reset

rst_n
This signal is an active-low input that initializes the RAM to zeros if the `rst_mode` parameter is set to 0, independent of the value of `cs_n`. If the `rst_mode` parameter is set to 1, `rst_n` does not affect the RAM, and should be tied HIGH or LOW. In this case, synthesis optimizes the design, and does not use the `rst_n` signal.

Attention If the technology library being used does not contain an active low D-latch with clear, synthesis gates the inputs of a D-latch with the rst_n signal, increasing the area of the design.

Application Notes

DW_ram_rw_a_lat is intended to be used as a small scratch-pad memory or register file. Because DW_ram_rw_a_lat is built from the cells within the ASIC cell library, it should be kept small to obtain an efficient implementation. If a larger memory is required, you should consider using a hard macro RAM from the ASIC library in use.

Timing Waveforms

The figures in this section show timing diagrams for various conditions of DW_ram_rw_a_lat.
